

WATTLE

Acacias of Australia

***Acacia orthotropica* Maslin, M.D.Barrett & R.L.Barrett**

Acacia orthotropica occurrence map.
Occurrence map generated via Atlas of Living
Australia (<https://www.ala.org.au>).

Common Name

Mt Trafalgar Wattle

Family

Fabaceae

Distribution

Occurs in the Kimberley region of northern W.A. where it is known from only a single population in Prince Regent Natl Park.

Description

Obconic, single-stemmed tree to 4 m tall. Branchlets terete, reddish brown, glabrous. Phyllodes narrowly oblong-ob lanceolate, straight, 3–6 cm long, (2.5–)3–5 mm wide, obtuse-mucronate, thinly coriaceous, erect, crowded, somewhat imbricate when dry, glabrous; longitudinal nerves 2 with central one the most pronounced and confluent with lower margin at base, second nerve extending for 2/3–3/4 length of phyllode, secondary nerves openly anastomosing; gland single, 1–3 mm above the pulvinus. Inflorescences simple, initiated within axil of immature phyllodes on new shoots; peduncles 20–30 mm long, slender, irregularly curved or sigmoid when dry, glabrous; heads globular, 30–35-flowered. Bracteoles c. 1 mm long, laminae puberulous with light golden and white hairs. Flowers 5-merous; calyx normally dissected to about the middle (sometimes to the base) into oblong, apically puberulous-hirsutulous lobes, the hairs light golden and white; petals with hairs at apex as on calyx. Pods (dehisced valves) oblong to narrowly oblong, mostly straight-edged, flat, 3–8 cm long, 14–16 mm wide, firmly chartaceous to very thinly crustaceous, glabrous, reticulately nerved, basal stipe 4–5 mm long. Seeds not seen but were seated in shallow, transverse depressions, each separated by a narrow septum.

Phenology

The type was at full anthesis in late Jan.

Habitat

Grows on a broken sandstone slope adjacent to a low basaltic hill, in open shrubland over dense *Triodia* spp. ground cover.

Specimens

W.A. [precise locality withheld for conservation reasons], 27 Jan. 2010, R.L.Barrett RLB 6527; holo: PERTH; iso: CANB, DNA, K, MEL, NSW, PERTH.

Notes

Most closely related to *A. kenneallyi* despite its superficially dissimilar appearance; see B.R.Maslin, M.D.Barrett & R.L.Barrett, *Nuytsia* 23: 572 (2013), for discussion. *Acacia kenneallyi* is easily distinguished by its pruinose branchlets, much larger, narrowly elliptic phyllodes, often racemose or paniculate inflorescences with more numerously-flowered heads and longer pods with obliquely arranged seeds. Phyllodes superficially similar to those of the arid zone species *A. jensenii* and some forms of *A. melleodora* but the relationship is seemingly not close. The latter two species are resinous shrubs with a small gland at their phyllode apices, 3/4-united sepals which, together with the petals, are glabrous.

Conservation

Acacia orthotropica is listed as Priority Two under Department of Parks and Wildlife Conservation Codes for Western Australian Flora.
